

Connect a Web App to Amazon Aurora

Ahmed Tetteh

Aurora and RDS > Databases > Create database

Create database [info](#)

Choose a database creation method

☒ **Full configuration**
You set all of the configuration options, including ones for availability, security, backups, and maintenance.

☐ **Easy create**
Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Engine options

Engine type [info](#)

☒ **Aurora (MySQL Compatible)**

☐ Aurora (PostgreSQL Compatible)

☐ MySQL

☐ PostgreSQL

☐ MariaDB

☐ Oracle

☐ Microsoft SQL Server

☐ IBM Db2

Engine version

Aurora MySQL 5.10.3 (compatible with MySQL 8.0.42) - default for major version 8.0

☐ **Enable RDS Extended Support** [info](#)
Amazon RDS Extended Support is a paid offering. By selecting this option, you consent to being charged for this offering if you are running your database major version past the RDS end of standard support date for that version. Check the end of standard support date for your major version in the [Amazon Aurora documentation](#).

Templates

Choose a sample template to meet your use case.

☐ **Production**
Use defaults for high availability and fast, consistent performance.

☒ **Dev/Test**
This instance is intended for development use outside of a production environment.

Introducing Today's Project!

What is Amazon Aurora?

Amazon Aurora is a type of relational database that stores highly related data in rows and columns (tabular format), and why it is useful because it provides higher performance for more demanding workloads than the standard DB engines.

How I used Amazon Aurora in this project

In today's project, I used Amazon Aurora to create a MYSQL database and store all my user data for my web server.

One thing I didn't expect in this project was...

One thing I didn't expect in this project was for the MYSQL database to have many configurable options to tweak the DB to your liking, and for it to easily connect to a computing resource, making your job as a developer easier- no need to login to your EC2 instance and install a plugin or third-party tool before you can connect to it.

This project took me...

It took me approximately 30 mins to complete this project.

In the first part of my project...

Creating an Aurora Cluster

A relational database is a database that organizes data in a tabular form, which are simply collections of rows and columns. They are called relational because the rows and columns relate to one-another.

Aurora is a good choice when we need something large-scale, with peak performance and uptime.

Choose a sample template to meet your use case.

☐ **Production**
Use defaults for high availability and fast, consistent performance.

☒ **Dev/Test**
This instance is intended for development use outside of a production environment.

Halfway through I stopped!

I stopped creating my Aurora database because I needed an EC2 instance which will serve my web app to connect to the database.

Features of my EC2 instance

I created a new key pair for my EC2 instance because it provides me with a way to securely authenticate and access my EC2 instance. It simply allows you to login to your virtual computer and run your processes or commands on there.

When I created my EC2 instance, I took particular note of the Public IPv4 address, the storage volume, and the security configurations, including SSH access.

Then I could finish setting up my database

Connectivity [Info](#)

Compute resource
Choose whether to set up a connection to a compute resource for this database. Setting up a connection will automatically change connectivity settings so that the compute resource can connect to this database.

☐ Don't connect to an EC2 compute resource
Don't set up a connection to a compute resource for this database. You can manually set up a connection to a compute resource later.

☒ Connect to an EC2 compute resource
Set up a connection to an EC2 compute resource for this database.

EC2 instance [Info](#)
Choose the EC2 instance to add as the compute resource for this database. A VPC security group is added to this EC2 instance. A VPC security group is also added to the database with an inbound rule that allows the EC2 instance to access the database.

nextwork-ec2-instance-web-server

Aurora Database uses clusters because a cluster consists of many nodes or virtual resources working together to distribute the workload, ensuring your data to always be available. The Aurora DB consists of a primary DB for write requests and multiple read replicas for read requests such as SELECT and also to serve as back-ups.
